

A

Does the giant module survive?

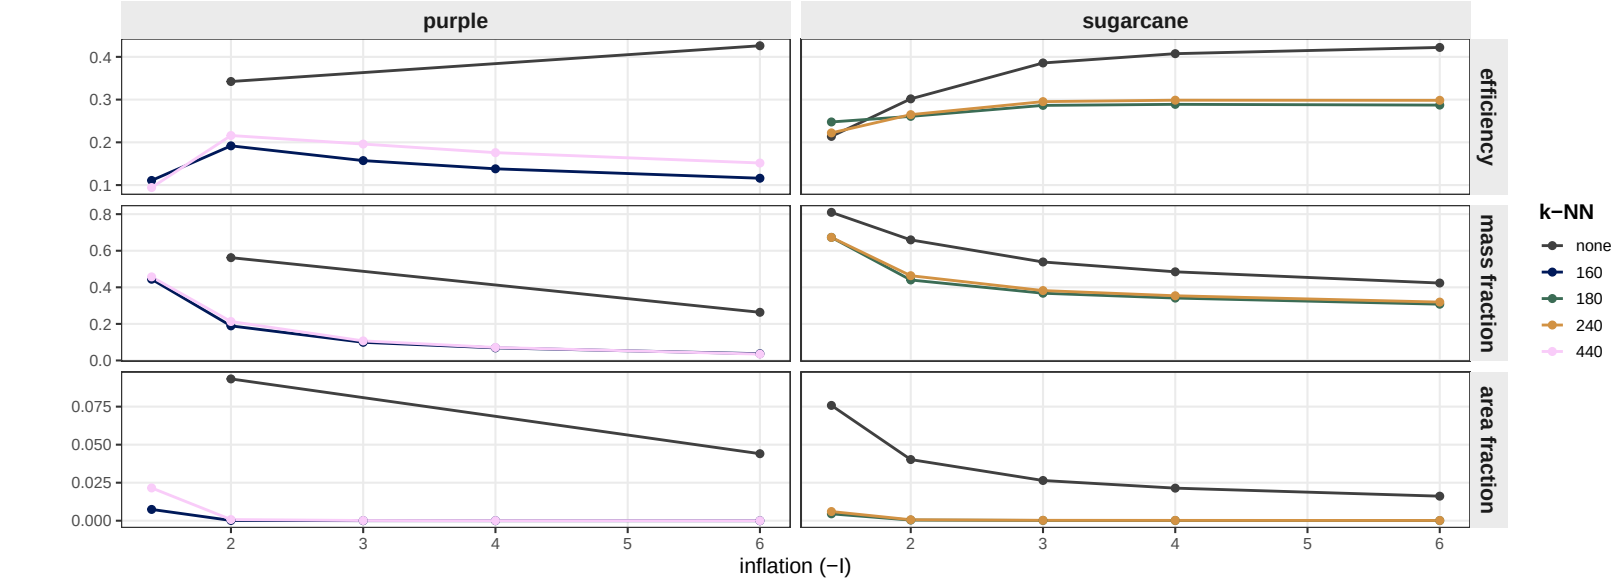

grey = no reduction, the pipeline's current setting. If inflation alone were the handle, that line would fall on its own.

B

clm info: the author's own criteria

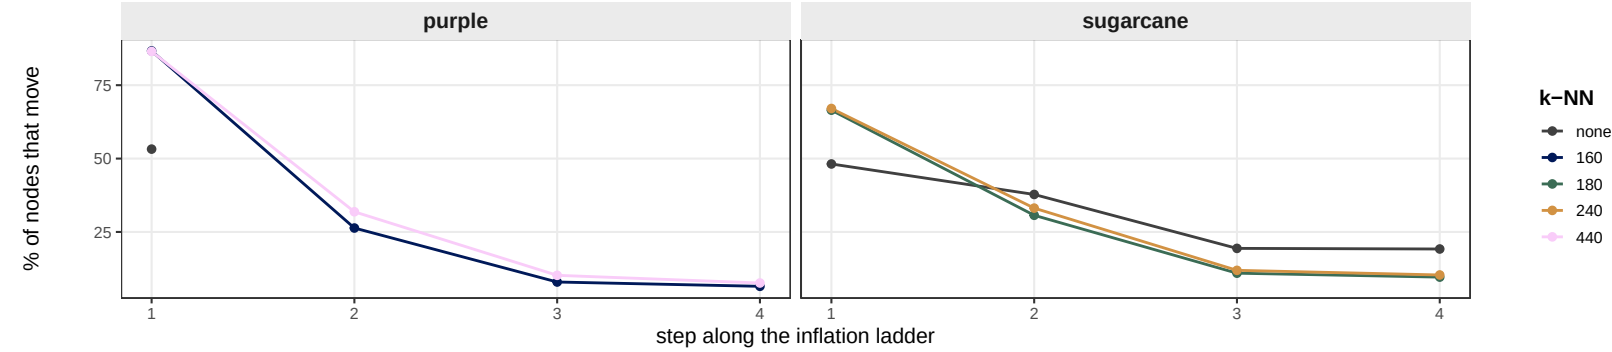

area fraction is the giant-module statistic; lower is finer-grained

C

clm dist: where the partition settles

a flattening curve means further inflation is buying nothing

D

Are the smaller modules actually more coherent?

zero = no better than a random partition of the same module sizes
